Conjecture (de Polignac, 1849)

For even integers h , there are infinitely many pairs of primes $p, p + h$.

We refer to such values of h as *de Polignac numbers*.

- What is the smallest de Polignac number?
- Do de Polignac numbers even exist???

It is widely conjectured that $h = 2$ is the smallest de Polignac number, i.e., that there are infinitely many pairs of **twin primes**.

Thus, we'd expect

$$\#\{p \leq x : p \text{ and } p + 2 \text{ prime}\} \approx \frac{x}{(\log x)^2}.$$

Since $\lim_{x \rightarrow \infty} \frac{x}{(\log x)^2} = \infty$, this gives us reason to believe that there are infinitely many pairs of twin primes!

The heuristic argument relies heavily on the assumption that the primes p are *uniformly distributed* among the residue classes $(\bmod q)$.

Let $\pi(x; q, a) := \#\{p \leq x : p \equiv a \pmod{q}\}$.

If the primes **were** uniformly distributed $(\bmod q)$, we'd expect:

$$\pi(x; q, a) \approx \frac{x}{\varphi(q) \log x},$$

when $\gcd(a, q) = 1$.

Definition

We say that a k -tuple (h_1, \dots, h_k) of nonnegative integers is *admissible* if it doesn't cover all of the possible remainders $(\text{mod } p)$ for any prime p .

Example: $(0, 2, 6, 8, 12)$ is an admissible 5-tuple.

Residue classes not covered:

$1 \pmod{2}$

$1 \pmod{3}$

$4 \pmod{5}$

$3 \pmod{7}$

$3 \pmod{11}$

Goal: Find values of n for which the tuple $n + h_1, \dots, n + h_k$ contains several primes.

Setup: For large N , look for n in the dyadic interval $[N, 2N)$.

Let $W := \prod_{p \leq \log_3 N} p$. Since \mathcal{H} is admissible, we can choose an integer ν so that $\gcd(\nu + h_i, W) = 1$ for all $1 \leq i \leq k$.

The W -trick: Pre-sieve the set to just those n satisfying $n \equiv \nu \pmod{W}$.

Thus, our sample space becomes

$$\Omega := \{N \leq n < 2N : n \equiv \nu \pmod{W}\}.$$

Let $w(n)$ denote nonnegative weights and let $\chi_{\mathcal{P}}$ denote the characteristic function of the set \mathcal{P} of primes. Consider

$$S_1 := \sum_{\substack{N \leq n < 2N \\ n \equiv \nu \pmod{W}}} w(n)$$

$$S_2 := \sum_{\substack{N \leq n < 2N \\ n \equiv \nu \pmod{W}}} \left(\sum_{i=1}^k \chi_{\mathcal{P}}(n + h_i) \right) w(n).$$

The fraction S_2/S_1 is a weighted average of the number of primes among $n + h_1, \dots, n + h_k$ over Ω .

primes

Theorem (Hall, Ph.D. 2006; Pollack, Ph.D. 2008)

If $q \geq 3$, then any $a \in \mathbb{F}_q$ (excluding $a = 0$) occurs infinitely often as a gap between irreducible polynomials.

$(q > 3$ due to Hall; $q = 3$ due to Pollack)

An improvement on Hall and Pollack's work

Theorem (Castillo, Hall, Lemke Oliver, Pollack, T., 2014)

Let $m \geq 2$. There is an integer $k_0 := k_0(m)$ such that for any admissible k -tuple (h_1, \dots, h_k) of polynomials in $\mathbb{F}_q[x]$ with $k \geq k_0$, there are infinitely many $f \in \mathbb{F}_q[x]$ such that at least m of $f + h_1, \dots, f + h_k$ are irreducible.

In a paper in 2013, Banks, Freiberg and Turnage-Butterbaugh used the Maynard-Tao method to give a strikingly simple re-proof of Shiu's result.

This begs the question: can the Maynard-Tao method be used to handle other “consecutive primes” problems?

For each k , let $d_k = p_{k+1} - p_k$.

Conjecture (Erdős, Turan 1948)

The sequence $\{d_k\}$ contains arbitrarily long (strictly) increasing runs and arbitrarily long (strictly) decreasing runs.

Same basic setup as in Maynard-Tao:

For large N , let $W := \prod_{p \leq \log_3 N} p$ and define

$$S_1 := \sum_{\substack{N \leq n < 2N \\ n \equiv \nu \pmod{W}}} w(n)$$

$$S_2 := \sum_{\substack{N \leq n < 2N \\ n \equiv \nu \pmod{W}}} \left(\sum_{i=1}^k \chi_{\mathcal{P}}(n + h_i) \right) w(n).$$

We want $\frac{S_2}{S_1} > m-1$ so that at least m of $n + h_1, \dots, n + h_k$ are prime for $n \in \Omega$.

Key innovation: **Modify the W-trick**

Fix $\mathcal{H} = \{h_1, \dots, h_k\}$ where $h_i = (i-1)(2k)!$. With this \mathcal{H} , we want to choose $\nu \pmod{W}$ such that:

- 1 (Consecutive Primes) For $n \in \Omega$, any prime $[n + h_1, n + h_k]$ is in $n + \mathcal{H}$.
- 2 (Decreasing φ values) With probability $1 + o(1)$,

$$\frac{n + h_i - 1}{\varphi(n + h_i - 1)} \in (2^{4i}, 2^{4i+3}]$$

for $1 \leq i \leq k$.

Theorem (Pollack, T., 2015)

Let $f = \varphi, \sigma, \omega, \Omega, \tau$. There are arbitrarily long runs of consecutive primes p on which $f(p-1)$ is decreasing. The same holds for $f(p-1)$ increasing.

Variation	Modification
Increasing φ 's	Replace \mathcal{H} with $-\mathcal{H}$
Increasing σ 's	Replace $\frac{n+h_i-1}{\varphi(n+h_i-1)}$ with $\frac{\sigma(n+h_i-1)}{n+h_i-1}$.
Decreasing σ 's	Like increasing σ 's but replace \mathcal{H} with $-\mathcal{H}$.

****Need additional modifications to handle ω, Ω, τ .**

Definition

Let $s_g(n)$ denote the sum of the base- g digits of n .

Example: $s_{10}(523) = 5 + 2 + 3 = 10$

$$s_{10}(541) = 5 + 4 + 1 = 10$$

Question (Sierpinski, 1961): Are there arbitrarily long runs of consecutive primes p on which $s_g(p)$ is constant? increasing? decreasing?
