**Hecke operators** are a family of operators  $T_n$  (where  $(n, N) = 1$ ) that act on modular forms.

## Definition

If  $f \in M_k(N, \chi)$  then  $T_p(f) \in M_k(N, \chi)$  and its Fourier expansion is

$$(T_p(f))(z) = \sum_{n=0}^{\infty} (a_{np}(f) + \chi(p)p^{k-1}a_{n/p}(f))q^n.$$

That is,

$$a_n(T_p(f)) = a_{np}(f) + \chi(p)p^{k-1}a_{n/p}(f)$$

for  $f \in M_k(N, \chi)$ .

# Nice properties of Hecke operators

In general  $T_n$  satisfies:

$$T_{ab} = T_a \cdot T_b \text{ if } \gcd(a, b) = 1$$

$$T_{p^r} = T_{p^{r-1}} \cdot T_p - \chi(p) \cdot p^{k-1} T_{p^{r-2}}$$

We always have:

We always have:

- $T_n : S_k(N, \chi) \rightarrow S_k(N, \chi)$
- $T_n : E_k(N, \chi) \rightarrow E_k(N, \chi)$

## Definition

A modular form is an **eigenform** if for every prime  $p$  with  $(p, N) = 1$ , there exists a complex number  $\lambda_p$  such that

$$T_p(f) = \lambda_p \cdot f.$$

## Corollary

*For infinitely many  $n$ , we have  $\sigma_{\chi_1, \chi_2}^{k-1}(n) > 0$ . Similarly,  $\sigma_{\chi_1, \chi_2}^{k-1}(n) < 0$  holds for infinitely many  $n$ .*

## Corollary

*Let  $p_0$  represent the positive integer where the first sign change of  $\sigma_{\chi_1, \chi_2}^{k-1}(n)$  (from positive to negative) occurs. Then, for any fixed  $\varepsilon > 0$ , we have*

$$p_0 \ll_{\varepsilon} N^{\frac{1}{4\sqrt{\varepsilon}} + \varepsilon}.$$

## Theorem (Kowalski, Lau, Soundararajan, Wu, 2010)

Let  $N$  be squarefree and  $k \geq 2$  an even integer. Let  $\{\varepsilon_p\}$  be a sequence of signs. Let  $H_k^*(N, \chi)$  be the set of all normalized newforms in  $S_k(N, \chi)$ , where  $\chi$  is principal. For any  $\varepsilon$  with  $0 < \varepsilon < 1/2$ , there exists  $c > 0$  such that

$$\frac{1}{|H_k^*(N, \chi)|} \#\{f \in H_k^*(N, \chi) : \lambda_f(p) = \varepsilon_p \text{ for all } p \leq x, p \nmid N\} \geq \left(\frac{1}{2} - \varepsilon\right)^{\pi(x)}$$

for  $x = c\sqrt{(\log kN)(\log \log kN)}$ , provided  $kN$  is large enough.

## Theorem (Linowitz + T., 2015)

Let  $\mathcal{D} = \{(D_1, D_2) : |D_1 D_2| \leq x\}$ . Given a sequence of signs  $\varepsilon_i = \{0, \pm 1\}$ , we have

$$\frac{1}{|\mathcal{D}|} \#\{(D_1, D_2) \in \mathcal{D} : \operatorname{sgn} \sigma_{\chi_1, \chi_2}^{k-1}(p_i) = \varepsilon_i, 1 \leq i \leq k\}$$

$$\rightarrow \left( \prod_{\substack{\varepsilon_i=0 \\ 1 \leq i \leq k}} \frac{1}{(p_i + 1)^2} \right) \left( \prod_{\substack{\varepsilon_i \neq 0 \\ 1 \leq i \leq k}} \frac{p_i(p_i + 2)}{2(p_i + 1)^2} \right),$$

as  $x \rightarrow \infty$ .

# The first sign change on average

## Conjecture (Linowitz + T., 2015)

Let  $\eta(D_1, D_2)$  represent the smallest  $p_i$  for which  $\text{sgn } \sigma_{\chi_1, \chi_2}^{k-1}(p_i) = -1$ . As  $x \rightarrow \infty$ , one would expect

$$\frac{\sum_{|D_1 D_2| \leq x} \eta(D_1, D_2)}{\sum_{|D_1 D_2| \leq x} 1} \rightarrow \theta,$$

where

$$\theta := \sum_{\ell=1}^{\infty} \frac{p_{\ell}^2(p_{\ell} + 2)}{2(p_{\ell} + 1)^2} \prod_{i=1}^{\ell-1} \frac{2 + p_i(p_i + 2)}{2(p_i + 1)^2}.$$
